

100 products of
two divisor classes

six of them
 $\mathrm{Sp}(V, \psi)$ -invariant

the 32 tetrahedron monomials $e_S^{(1)} e_{T \setminus S}^{(2)}$,

1, 4, 6, 4, 1 by the number $|S|$ of factors from the first copy

with components in the Weil field k_c , the pull-backs of the Weil line
add one class per column, the ten sums $s_{\pm,k}$: 110 with the divisor products

components separating the four weights of a tetrahedron, as those of K_c^+ do,
reach every cell: 132

the exceptional classes lie in the twelve mixed cells, $|S| = 2$,
and in no combination of the $s_{\pm,k}$

the six mixed monomials $e_S^{(1)} e_{T \setminus S}^{(2)}$ of T_+ in three pairs, with $d_1 = (1, 1, 1)$, $d_2 = (1, -1, -1)$,
 $d_3 = (-1, 1, -1)$, $d_4 = (-1, -1, 1)$; grey: the coefficients ± 1 of $s_{\pm,2}$; blue: those of $\pi_{12} - \pi_{13}$, $a = (1, -1, 0)$
