

At an isolated double point of the support the translation classes multiply to a nonzero germ.

At every isolated double point of  $Z$ , of either kind, some constant bivector  $\pi$  has  $\text{ev}_{\mathcal{F}}(\pi) + \frac{d}{2}(\pi \lrcorner \Theta^2) \text{id} \neq 0$ ;  
 the class  $\pi + \frac{d}{2} \pi \lrcorner \Theta^2$  preserves  $\text{ch}(\mathcal{F})$ , so the weakened criterion fails for  $\mathcal{F}$  and for  $\Phi(\mathcal{F} \boxtimes \mathcal{F})$ .
