

The evaluation map carries the first-order symmetries of $\text{ch}(E)$ onto the whole kernel of σ_E .

$z \mapsto z \cdot \text{id}_E$ and $\pi \mapsto \frac{1}{2}\pi \sqcup \lambda_i^2$: both onto Δ
 $v \mapsto v \sqcup \lambda_i$: onto Σ ; T alone reaches 3 of its 6 dimensions

$$\mathrm{Ext}^2(E, E) = \bigoplus_{\dim 90}^6 H^{0,2}$$

$$HT^2(A_0) \cong HH^2(A_0), \quad \dim 66$$

$$\Delta = \{(z, \dots, z)\}, \quad \dim 9$$

$$\Sigma = \{(u_i a + \bar{u}_i b)_i\}, \quad \dim 6$$

$$\ker \sigma_E = \Delta \oplus \Sigma, \quad \dim 15, \text{ all of it in } \operatorname{im} \operatorname{ev}_E$$

the square commutes, so $\ker \sigma_E \cap \operatorname{im} \operatorname{ev}_E = \operatorname{ev}_E(\ker(x \mapsto x \lrcorner \operatorname{ch}(E)))$; for the explicit object this is all of $\ker \sigma_E$, so the weakened criterion fails by 15 dimensions; and $66 < 90$, so ev_E is not onto.
